Asthma is a chronic disorder in which airflow to the lungs is impeded by inflammation, increased secretions, and constriction. Asthma is the most common chronic condition of childhood. The incidence of asthma is increasing in the United States and industrialized countries worldwide. With it, the impact on families and the associated costs of medical care is also increasing.

Identification of asthma in infants and small children can be difficult. While wheezing is the hallmark of asthma in adults, recurrent cough may be the only observable symptom as asthma in a young child. Wheezing may be symptomatic of other pediatric conditions, such as:

- Foreign bodies
- Developmental malformations
- Respiratory infections
- Cystic fibrosis
- Gastroesophageal reflux
- Congenital heart disease

Early recognition and successful management of childhood asthma depends on a strong alliance between families and health care providers.
